

POTENTIAL BIOSURFACTANT-PRODUCING
BACTERIA ISOLATED FROM PETROLEUM SLUDGE

BY

NADHRAH ANNUAR

A thesis submitted in fulfilment of the requirement for the
degree of Master of Science (Biotechnology)

Kulliyyah of Science
International Islamic University Malaysia

MAY 2021

ABSTRACT

Biosurfactants are amphiphilic compounds produced by microorganisms with almost similar properties as chemically synthesized surfactants. With amphiphilic properties, these compounds are widely applied as bioemulsifier and enhancer in the bioremediation process. This study aimed to screen potential biosurfactant producers from petroleum sludge. Bacteria were isolated from petroleum sludge samples and screened for biosurfactant activity by analysing Emulsification activity (E_{24}) and Surface Tension of the culture supernatant. Selected isolates were subjected to 16S rRNA analysis while the isolate that showed the highest surface tension reduction was further subjected to the growth study. The effect of carbon and nitrogen source towards surface tension reduction was tested. Then, the biosurfactant produced was partially purified and characterized. Out of the 47 isolates, *Pseudomonas* sp. P15 exhibited among the highest emulsification index (67.41%) and biosurfactant activity by reducing the surface tension measurement as low as 18.92 mN/m. In the bacterial growth study, *Pseudomonas* sp. P15 exhibited the highest surface tension reduction when 2% of used engine oil (UE2) was used as the carbon source. The addition of nitrogen source, 0.5% of yeast extract did not affect the surface tension reduction but increased the bacteria growth and biosurfactant yield by 100-fold (43.37 g/L). After liquid-liquid extraction, the partially purified biosurfactant showed similar R_f value to the rhamnolipid standard in the thin layer chromatography (TLC) and effectively emulsified the hydrocarbon substrate. The finding indicated that *Pseudomonas* sp. P15 isolated from petroleum sludge has potential to produce biosurfactant that can be used in wide range of industrial application such as bioremediation of petroleum contaminated sites and enhance the oil recovery in the petroleum industry.

خلاصة البحث

إن منشطات السطح الحيوية، أو المواد الفعالة سطحياً، هي مركبات مزدوجة تنتجها كائنات دقيقة لها خواص مشابهة تقريباً لمنشطات السطح المصنعة كيميائياً. وبفضل خصائص الازدواج فإن هذه المركبات تستخدم على نطاق واسع كمستحلبات ومحسّنات في عملية المعالجة الحيوية. استهدفت هذه الدراسة فحص مُنتجات منشطات السطح الحيوية المحتملة من الحمأة البترولية. تم عزل البكتيريا من عينات الحمأة البترولية وفحص نشاط المواد الفعالة سطحياً عن طريق تحليل نشاط الاستحلاب (E24) والتوتر السطحي للسائل الرائق من المزرعة البكتيرية. وخضعت العينات المختارة لتحليل الحمض النووي الريبوسومي S16، بينما تمّ تعريض العزلة التي أظهرت أعلى انخفاض في التوتر السطحي لمزيد من دراسة النمو. وتمّ اختبار تأثير كلٍّ من مصدر الكربون والنتروجين على تقليل التوتر السطحي، وتمّ بعد ذلك التنقية الجزئية وتوصيف منشط السطح الحيوي المنتج. ومن بين 47 عزلة، تم اختيار العزلة P15 كمنتج محتمل لمنشط السطح الحيوي. وأظهرت بكتيريا *Pseudomonas sp. P15* مؤشر استحلابٍ أعلى (67.41%) ونشاطاً سطحياً عن طريق خفض قياس التوتر السطحي إلى 18.92 مل نيوتن/م. وأظهرت *Pseudomonas sp. P15* في دراسة نموّ البكتيريا أعلى انخفاض في قيمة التوتر السطحي حين تمّ استعمال 2% من زيت المحرك المستخدم (UE2) كمصدر للكربون، ولم تؤثر إضافة مصدر النيتروجين - 0.5% من مستخلص الخميرة - على تقليل التوتر السطحي ولكنها أدت إلى زيادة نمو البكتيريا ومردود منشط السطح الحيوي بمقدار مئة ضعف (43.37 جم/لتر). وبعد عملية استخلاص السائل أظهر منشط السطح الحيوي المنقى جزئياً قيمةً لمعامل R_f ماثلةً لقيمة مرجع *rhamnolipid* في كروماتوجرافيا الطبقة الرقيقة (TLC)، كما استحلّب الركيزة الهيدروكربونية بشكلٍ فعال. وأشارت النتائج إلى أنّ بكتيريا *Pseudomonas sp. P15* المعزولة من الحمأة البترولية لديها القدرة على إنتاج منشط سطحي والذي يمكن استخدامه في مجموعة واسعة من التطبيقات الصناعية مثل المعالجة الحيوية للمواقع الملوثة بالبتروول وتعزيز استخلاص النفط في الصناعة البترولية.

SPECIAL DEDICATION,

To my beloved husband

*who always cheer me up, bear with all the dramas and lean the ears to hear my
stories even though this is not your forte,*

To my wonderful parents

*who have portrayed their own dedication pursuing journey in their life,
encouraged me to do well too in my journey.*

ACKNOWLEDGEMENTS

In the name of Allah, The entirely Gracious and the Most Merciful. All praises to Allah SWT. May He send peace and blessing to our Prophet Muhammad, his family and his companions. All praises to Allah for His love and guidance in giving me the strength and determination to complete this research. Alhamdulillah for your great plans, with his permission, I am able to accomplish this journey.

I would like to take this opportunity in expressing my highest gratitude to my supervisor, Asst. Prof. Dr Mardiana Mohd Ashaari and my co-supervisor, Assoc. Prof. Ts. Dr Suhaila Mohd Omar for all their willingness to assist, listen and guide in every way, in the midst of their heavy responsibilities and duties. Not forgetting Asst. Prof. Dr Siti Fairuz Che Othman for willingness to help and guide me in statistical analysis. Above of all, thank you for all their guidance, support, ideas, motivation and encouragement which have develop my understanding in this research. I have learnt so much great things from them and I am blessed to have such the dedicate and understanding supervisory committee.

My sincere appreciation as well to the lab research officers and lab assistants, especially to Sis. Muiezzah, Bro. Yahya, Bro. Masrul, Bro. Halim, and Bro. Muzammil for their guidance and cooperation throughout my laboratory works. Not forgetting Sis. Zailillah and Bro. Hanif from Kulliyah of Pharmacy (KOP) for permitting to use their equipment and facility. A special tribute to my FYP students, fellow lab mates and all the PGKOSS especially the members in the postgraduate room for the friendship and assistance they have offered.

Special dedication to all my sisters in PEMBINA IIUMK especially Sis. Nik Ilya who is always offered hands and accompany in the lab when I have to stay back until night or on the weekend. Honourable appreciation to all my *liqa'* members who are always remind me, this journey is one of *ibadah* to worship Allah SWT. To my dearest sister and mentor, Sis. Wan Syafiqah Meor Hissan who always keeps the positive vibes, encourage and guide me from the day one until the very end of my master journey. Thank you for being there for me and may Allah reward all your kindness.

To my parents; Annuar Salleh and Wan Nor Adibah Wan Ahmad, my parents in-laws; Rushdan Abdul Halim and Norhayati Ahmad Salleh and all my sibling and in-laws, this research would not be accomplished without your consent and support. Thank you for love, encouragement and constantly support. Last but not least, all my gratitude goes to the most understanding husband, Muaz Rushdan who is always being my number one supporter. Thank you for always letting me in discovering my potential and push me to the fullest. I am very glad to have you as my pillars of strengths. In this very challenging journey, *Alhamdulillah* I have all of them as the wonderful support system that I could not substitute with the others.

To those who have been involved in this research, directly and indirectly, Thank you so much and only Allah SWT is the only One would repay you with all the kindness.

INTRODUCTION

1.1 BACKGROUND OF THE STUDY

Surfactants are amphiphilic compounds that consist of hydrophilic (head) and hydrophobic (tails) end which make it soluble in water, lipids or oil (Migahed & Al-Sabagh, 2009). Due to their properties, these compounds have a speciality in reducing surface and interfacial tension between two liquids which have a different degree of polarity and hydrogen bonds such as oil and water interfaces. The surfactants are widely used in the petroleum industry, food, pharmaceutical, cosmetics and detergent. Surfactants can be classified based on their origin; chemically synthesized surfactants and biological surfactants or called as biosurfactants. There is an increase of interests in biosurfactants production as an alternative to the chemically synthesized surfactants. The highly branched synthetic surfactant's structure makes it hard to degrade and lead to less bioavailability to the environment compared to biosurfactants (Shoeb et al., 2013).

Biosurfactants are amphiphilic compounds produced by microorganisms with almost similar properties as chemically synthesized surfactants (Banat, 1995; Pornsunthorntawe et al., 2008; Yin et al., 2009). Biosurfactants have low toxicity, more biodegradable and environmental-friendly (Ainon et al., 2013; Saisa-Ard et al., 2013). Since biosurfactants have very low critical micelle concentration (CMC) than chemically made surfactants, the biosurfactants are effective at low concentrations and able to reduce the surface and interfacial tensions between water or air, air or oil and water or oil (Migahed & Al-Sabagh, 2009).

Compared to other microorganisms including fungi and yeast, bacteria are known as major biosurfactants producers that extensively produce biosurfactants as secondary metabolites. Among the well-known types biosurfactants produced by biosurfactant producers namely glycolipids, rhamnolipids and surfactin. Rhamnolipid biosurfactants is one of the biosurfactants that commonly produced by *Pseudomonas aeruginosa* (Antoniou et al., 2015; Bharali & Konwar, 2011; Cameotra & Singh, 2008), surfactin by *Bacillus subtilis* (Pereira et al., 2013) and other glycolipids (Noparat et al., 2014). Biosurfactants producer or called as biosurfactant-producing bacteria are likely found in the environment that contains rich hydrocarbon and favourable condition such as oil reservoir (Chandankere et al., 2013), soil (Almansoori et al., 2019; de Faria et al., 2011; Zambry et al., 2017) ocean (Ismail et al., 2018), hot spring (Suthar & Nerurkar, 2016) or wastewater (Affandi et al., 2014). Other than that, microbial resources from palm oil industry such as palm oil mill effluent (POME) (Marajan et al., 2015) and palm oil-contaminated soil (Saisa-ard et al., 2014) are also potential biosurfactant producers due to the presence of carbon source in oil palm products.

Additionally, the biosynthesis of biosurfactants is depending on the fermentation conditions and environmental factors. The biosurfactant-producing bacteria require enough nutrients in terms of carbon and nitrogen sources to generate energy for their growth. As mentioned by Bertrand et al. (2018), carbon and nitrogen sources are the most important parameters for biosurfactants production followed with other physical parameters such as temperature, pH and presences of trace metal. Several types of raw materials, either water-soluble or insoluble substances, have been used as a carbon source in biosurfactants production include crude oil, diesel, oily sludge, glucose, sucrose and glycerol. As mentioned by Chandankere et al. (2013), crude oil was used as a carbon source in biosurfactant production by *Bacillus methylotrophicus*

USTBa. The presence of crude oil in the fermentation process increased the emulsification activity up to 78% and 1.8 g/L of biosurfactants productions. The combination of n-hexadecane as carbon source and urea as nitrogen source in the production of biosurfactants by *Pseudomonas aeruginosa* OBP1 showed 4.8 g/L of maximum yield (Bharali & Konwar, 2011).

1.2 PROBLEM STATEMENT

Biosurfactants are widely used as an alternative to chemically synthesized surfactants. Due to their amphiphilic nature, these compounds are able to alter two different polarities of surfaces such as water/air, oil/air, or oil/water surfaces. With these physicochemical properties, a Japanese chemical company namely Kaneka Corp has developed surfactin biosurfactants to disinfect the polluted area affected by the Fukushima nuclear (Sajna et al., 2015). In Malaysia, the Petrochemical Industry is known as one of the largest sectors that provides essential products such as crude oil and natural gas. However, environmental pollution occurred throughout the petroleum production process such as oil spill, contamination in soils and water. As in conventional methods, chemically synthesized surfactants are used in remediation process. However, the application of chemically synthesized surfactants would create other environmental problems. There is urgency on producing biosurfactants produced by microorganisms to overcome those problems. The application of biosurfactants are profoundly more environmental-friendly and biodegradable. Therefore, this research was carried out to find out new potential biosurfactants producer isolated from petroleum sludge due to lack information on bioprospecting novel biosurfactant compounds produced by bacteria isolated from the contaminated environment.

1.3 RESEARCH OBJECTIVES

1.3.1 General Objective

To screen potential biosurfactant producers from petroleum sludge.

1.3.2 Specific Objectives

- i. To isolate the potential biosurfactant producers from the petroleum sludge.
- ii. To screen biosurfactant activity using Emulsification Index (E_{24}) and Surface Tension Measurement.
- iii. To determine the effect of carbon and nitrogen sources towards surface tension reduction of the selected biosurfactant producers.
- iv. To determine the specific types of biosurfactant produced.

1.4 RESEARCH HYPOTHESIS

- i. Isolates that able to thrive in the medium containing 2% of crude oil will have biosurfactant activity.
- ii. The lower the surface tension measurement the higher the chance that the isolate is a biosurfactant producer.
- iii. Different types of carbon and nitrogen source will affect the reduction of surface tension measurement.
- iv. The R_f value of the biosurfactant in the TLC will differentiate the type of biosurfactant produced.

1.5 RESEARCH QUESTIONS

- i. How many isolates that can be determined as potential biosurfactant-producing bacteria isolated from the petroleum sludge?
- ii. How many of the isolates are able to exhibit biosurfactant activity?
- iii. Which type of carbon and nitrogen sources that able to reduce surface tension measurement?
- iv. What types of biosurfactant produced by the selected biosurfactant producer?

CHAPTER TWO

LITERATURE REVIEW

2.1 CLASSIFICATION OF BIOSURFACTANTS

As amphipathic substances, biosurfactants able to adsorb and alters the conditions in or between interfaces. These surfactants produced by microorganisms can be divided into low-molecular-weight molecules and high-molecular-weight polymer based on their chemical properties and types of biosurfactants producers. As mentioned by Ron and Rosenberg (2001), biosurfactants that classified as low-molecular-weight surfactants are generally glycolipids or lipopeptides with simple fatty acids and phospholipids, which is efficiently reduce the surface and interfacial tension. Polymeric surfactants and particulate biosurfactants are high-molecular-weight biopolymers, which is tightly attached towards the surface and these group of biosurfactants can react effectively as emulsion stabilizing agents.

2.1.1 Glycolipids

Glycolipids biosurfactant compose of carbohydrates like mono-, di-, tri- and tetrasaccharides that linked with hydroxyls fatty acids or long-chain fatty acids connected with either an ester or ether group (Shoeb et al., 2013; Vandana & Singh, 2018). The best examples of glycolipids are rhamnolipids, sophorolipids, trehalose lipids and mannosylerythritol. Figure 2.1 showed the structures of common glycolipids biosurfactant.

(A)

(B)

(C)

Figure 2.1 Structure of Common Glycolipids Biosurfactants. (A) Rhamnolipid. (B) Trehalolipid. (C) Sophorolipid (Patel et al., 2019; Sharma 2016)

One of the most studied glycolipids-biosurfactants are rhamnolipids that consists of one or two molecules of rhamnose sugar which are linked together with β -hydroxydecanoic acids as shown in Figure 2.1(A) (Shoeb et al., 2013). Commonly, rhamnolipids are produced by *Pseudomonas* species that isolated from hydrocarbon-contaminated environments such as *Pseudomonas aeruginosa* from petroleum sludge (Bharali & Konwar, 2011) and *Pseudomonas stutzeri* from Palm Oil Mill Effluent (Fazli & Hertadi, 2019). In another study, it was reported that rhamnolipids were produced by a microbial consortium consist of the Gram-negative *P. aeruginosa* and Gram-positive *Rhodococcus* sp., which facilitated the degradation of hydrocarbon compounds (Cameotra & Singh, 2008). With its speciality in reducing surface and interfacial tension, rhamnolipid biosurfactants were also used to reclaim oil from the reservoir (Yan et al., 2012).

Other microorganisms such as yeasts that belong to genus *Candida* and *Torulopsis* were reported produced glycolipids biosurfactants (Ron & Rosenberg, 2001). These biosurfactants were known as sophorolipids that consist of dimeric carbohydrate sophorose linked through a glycosidic bond to a long-chain hydroxy fatty acid (Figure 2.1 (C)) (Santos et al., 2016). These biosurfactants are bind together by at least six to nine varieties of hydrophobic sophorolipids that are a mixture of free acid form and macrolactones. The structure of sophorolipids can be vary depending on the types of carbon sources. Sophorolipids produced by *Candida bombicola* has potential to be used as antibacterial and antibiofilm agents due to its ability to disrupt the formation of biofilm and prevent the adhesion (De Rienzo et al., 2015).

However Kitamoto et al. (1993), reported that other productive yeast strains known as *Candida antarctica* was producing mannosylerythritol lipids (MEL), yeast glycolipids to exhibit the antimicrobial activity towards Gram-positive bacteria. These

yeast strains also called as *Pseudozyma antarctica* isolated from vegetable oils produced mannosylerythritol lipids to facilitate in removal and biodegradation of hydrocarbon (Kitamoto et al., 2001). On the other hand, mannosylerythritol produced by *Saccharomyces cerevisiae* used as bioemulsifier in mayonnaise formulation (Alizadeh-Sani et al., 2018). These biosurfactants were formed by polypeptide chains linked together with short and long mannose bonds.

Trehalose lipids is one of the glycolipids biosurfactant produced by several microorganisms belonged to the mycolates groups including *Mycobacterium*, *Nocardia* and *Corynebacterium* (Desai & Banat, 1997; Sen, 2010). Trehalolipids contains non-reducing disaccharide trehalose combined at C-6 and C-6 of mycolic acids as elucidated in Figure 2.1 (B) (Shoeb et al., 2013). The structure of trehalose lipids is different depends on the microorganism producer. Mycolic acids are long-chain, α -branched- β -hydroxy fatty acids that found in the cell wall of the mycolata taxon or a group of bacteria which is mostly species of *Mycobacterium* (Franzetti et al., 2010). In other study, *Rhodococcus erythropolis* was reported to be one of the trehalose lipids producers that increase the solubility and biodegradation of phenanthrene (PHE) (Chang et al., 2004).

2.1.2 Lipopeptides

Most well-studied lipopeptides were synthesized by bacterial and actinomycetes species. These lipopeptides antibiotic-like biosurfactants are promising as antimicrobial agents. Lipopeptides surfactants are generally contained of a high amount of cyclic lipopeptides that linked to a fatty acid. The best examples of lipopeptides biosurfactants such as surfactin, iturin, fengysin and lichenysin. Both surfactin and iturin are known
